DATE Nov. 25, 1998 EXPRESS MAIL NO. EI796816534US

CERTIFICATE OF MAILING BY EXPRESS MAIL

I hereby certify that the below identified Application and attached documents, pursuant to 37 CFR 1.10, are being deposited as "Express Mail" this date with the United States Postal Service in an envelope addressed to the Commissioner of Patents and Trademarks, Washington DC 20231,

By

George R. Corrigan

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

FILING OF PATENT APPLICATION PURSUANT TO 37 CFR 1.53(b)

Docket No.: ITW 7188B

Box Patent Application
Honorable Commissioner of Patents and Trademarks
Washington, D.C. 20231

Sir:

Herewith is the patent application of Applicant(s):
James Thommes

FOR: Method And Apparatus For Receiving A Universal Input Voltage
In A Welding Power Source

This new application is
a continuation of, and claims the benefit of the filing date of,
U.S. Patent Application Serial No. 08/779,044, filed January 6,
1997, entitled Method And Apparatus For Receiving A Universal
Input Voltage In A Welding Power Source, which is a continuation
of, and claims the benefit of the filing date of, U.S. Patent
Application Serial No. 08/342,378 filed November 18, 1994,
entitled Method And Apparatus For Receiving A Universal Input
Voltage In A Welding Power Source, which issued on Feb. 11, 1997,
as Patent No. 5,601,741.

Including a copy of the prior application as filed, consisting
of:

Declaration
1 page Abstract
24 Pages of Specification and Claims
4 Sheet(s) of informal drawing

A copy of the change of power of attorney is also enclosed.

The undersigned hereby verifies that the foregoing papers
are a true copy of what is shown in our records to be the above
identified prior application, including the oath or declaration
originally filed.

11/25/98
JC511 U.S. PTO

JC518 U.S. PTO
09/200058
11/25/98

Amendments:

Please amend the subject application to include the following cross-reference to related application: This is a continuation of Application No. 08/779,044 filed on January 6, 1997, which is a continuation of, and claims the benefit of the filing date of, U.S. Patent Application Serial No. 08/342,378 filed November 18, 1994, entitled Method And Apparatus For Receiving A Universal Input Voltage In A Welding Power Source, which issued on Feb. 11, 1997, as Patent No. 5,601,741.

Assignment

The prior application is assigned of record to Illinois Tool Works Inc.

Copendency of Prior Application:

A petition, fee and response has been filed to extend the term of the pending prior application until November 26, 1998.

Power of Attorney:

The Power of Attorney in the prior application was changed to the undersigned in papers filed during the prosecution of the prior application.

**THE FOLLOWING FILING FEE IS BASED ON CLAIMS AS FILED
LESS ANY ABOVE CANCELED
PER MPEP SEC. 506 AND SEC. 607**

Fee Calculation:

Basic Fee (\$760)		=	\$760.00
Total Claims	24 minus 20 = 4	x \$ 18.00 =	+\$ 72.00
Independent Claims	3 minus 3 = 0	x \$ 78.00 =	+\$ 0.00
TOTAL FILING FEES:			<u>=\$832.00</u>

If additional fees are due please charge Deposit Account number 50-0599.

5 Briarcliff Court
Appleton, WI 54915

(920) 954-1099

SPECIFICATION

METHOD AND APPARATUS FOR RECEIVING A UNIVERSAL
INPUT VOLTAGE IN A WELDING POWER SOURCE

FIELD OF THE INVENTION

5 This invention generally relates to power
sources. More particularly, this invention relates to
inverter power sources employed in welding, cutting and
heating applications.

10 Power sources typically convert a power input
to a necessary or desirable power output tailored for a
specific application. In welding applications, power
sources typically receive a high voltage alternating
current (VAC) signal and provide a high current output
welding signal. Around the world, utility power supplies
(sinusoidal line voltages) may be 200/208V, 230/240V,
15 380/415V, 460/480V, 500V and 575V. These supplies may be
either single-phase or three-phase and either 50 or 60
Hz. Welding power sources receive such inputs and
produce an approximately 10-40 volt dc high current
welding output.

20 Welding is an art wherein large amounts of
power are delivered to a welding arc which generates heat
sufficient to melt metal and to create a weld. There are
many types of welding power sources that provide power
suitable for welding. Some prior art welding sources are
25 resonant converter power sources that deliver a
sinusoidal output. Other welding power sources provide a
squarewave output. Yet another type of welding power
source is an inverter-type power source.

30 Inverter-type power sources are particularly
well suited for welding applications. An inverter power

source can provide an ac square wave or a dc output. Inverter power sources also provide for a relatively high frequency stage, which provides a fast response in the welding output to changes in the control signals.

5 Generally speaking, an inverter-type power source receives a sinusoidal line input, rectifies the sinusoidal line input to provide a dc bus, and inverts the dc bus and may rectify the inverted signal to provide a dc welding output. It is desirable to provide a
10 generally flat, i.e. very little ripple, dc bus. Accordingly, it is not sufficient to simply rectify the sinusoidal input; rather, it is necessary to also smooth, and in many cases alter the voltage of, the input power. This is called preprocessing of the input power.

15 There are several types of inverter power sources that are suitable for welding. These include boost power sources, buck power sources, and boost-buck power sources, which are well known in the art.

 Generally, a welding power source is designed
20 for a specific power input. In other words, the power source cannot provide essentially the same output over the various input voltages. Further, components which operate safely at a particular input power level are often damaged when operating at an alternative input
25 power level. Therefore, power sources in the prior art have provided for these various inputs by employing circuits which can be manually adjusted to accommodate a variety of inputs. These circuits generally may be adjusted by changing the transformer turns ratio,
30 changing the impedance of particular circuits in the power source or arranging tank circuits to be in series or in parallel. In these prior art devices, the operator was required to identify the voltage of the input and then manually adjust the circuit for the particular
35 input.

 Generally, adapting to the various voltage inputs in the prior art requires that the power source be opened and cables be adjusted to accommodate the

particular voltage input. Thus, the operator was required to manually link the power source so that the appropriate output voltage was generated. Operating an improperly linked power source could result in personal injury, power source failure or insufficient power.

Prior art devices accommodated this problem by configuring the power source to operate at two different VAC input levels. For example, U.S. Patent No.

4,845,607, issued to Nakao, et al. on July 4, 1989,

discloses a power source which is equipped with voltage doubling circuits that are automatically activated when the input is on the order of 115 VAC, and which is deactivated when the input is on the order of 230 VAC. Such sources are designed to operate at the higher voltage level, with the voltage doubling circuit providing the required voltage when the input voltage is at the lower level. This type of source, which uses a voltage doubling circuit, must use transistors or switching devices as well as other components capable of withstanding impractical high power levels to implement the voltage doubling circuit. Further, the circuitry associated with the voltage doubling circuit inherently involves heat dissipation problems. Also, the voltage doubling circuit type of power source is not fully effective for use in welding applications. Thus, there exists a long felt need for a power source for use in welding applications which can automatically be configured for various VAC input levels.

Welding power sources are generally known which receive a high VAC signal and generate a high current dc signal. A particularly effective type of the power source for welding applications which avoids certain disadvantages of the voltage doubling circuit type of power source generally relies on a high frequency power inverter. Inverter power sources convert high voltage dc power into high voltage AC power. The AC power is provided to a transformer which produces a high current output.

Power inverters for use over input voltage ranges are generally known in the art. For example, a power inverter which is capable of using two input voltage levels is disclosed in U.S. Patent No. 3,815,009, issued to Berger on June 4, 1974. The power inverter of that patent utilizes two switching circuits; the two switching circuits are connected serially when connected to the higher input voltage, but are connected in parallel to account for the lower input voltage. The switching circuits are coupled to each other by means of lead wires. This inverter is susceptible to operator errors in configuring the switching circuits for the appropriate voltage level, which can result in power source malfunction or human injury.

Other prior art welding sources that improved upon manual linking provided an automatic linkage. For example, the Miller Electric AutoLink is one such power source and is described in U.S. Patent 5,319,533 incorporated herein by reference. Such power sources test the input voltage when they are first connected and automatically set the proper linkage for the input voltage sensed. Such welding power sources, if portable, are generally inverter-type power sources, and the method by which linking is accomplished is by operating the welding power source as two inverters. The inverters may be connected in parallel (for 230V, for example) or in series (e.g., for 460V). Such arrangements generally allow for two voltage connection possibilities. However, the higher voltage must be twice the lower voltage. Thus, such a power source cannot be connected to supplies ranging from 230V-460V to 380V-415V or 575V.

A 50/60 Hz transformer could be used to provide multiple paths for various input voltages. It would, however, have the disadvantage of being heavy and bulky compared to an inverter-type welding power source of the same capacity. In addition, if it was automatically linked as in the Miller AutoLink example given above, it would have to have link apparatus for each voltage. Such

an automatic linkage would be complicated and probably uneconomical for the range of voltages contemplated by this invention. Thus, it is unlikely that prior art power sources that automatically select the proper of two
5 input voltage settings will accommodate the full range of worldwide electrical input power. This shortcoming may be significant in that many welding power sources are purchased to be transportable from site to site. The ability to automatically adapt to a number of input power
10 voltage magnitudes is thus advantageous.

It is, therefore, one object of this invention to provide a welding power source that receives any of the above-mentioned input voltages, or any other input voltage, without the need of any linkages, whether manual
15 or automatic. Additionally, it is desirable to have such a welding power source that incorporates inverter technology and without using high power 50/60 Hz transformers.

SUMMARY OF THE INVENTION

The present invention is a power source that is
20 capable of receiving any input voltage over a wide range of input voltages. The power source includes an input rectifier that rectifies the ac input into a dc signal. A dc voltage stage converts the dc signal to a desired dc
25 voltage and an inverter inverts the dc signal into a second ac signal. An output transformer receives the second ac signal and provides a third ac signal that has a desired current magnitude. Although not necessary, the output current may be rectified and smoothed by an output
30 inductor and an output rectifier. A controller provides control signals to the inverter and an auxiliary power controller is capable of receiving a range of input voltages and provides a control power signal to the controller.

A method for providing a welding current
35 includes rectifying an ac input and providing a first dc signal. The first dc signal is then converted into a

second ac signal. Then the second ac signal is converted into a third ac signal that has a current magnitude suitable for welding. The welding current may then be rectified and smoothed to provide a dc welding current and an auxiliary power signal is supplied at a preselected control power signal voltage, regardless of the magnitude of the ac input signal.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a block diagram of the preferred embodiment of the present invention;

Figure 2 is a detailed diagram of the input rectifier of Figure 1;

Figure 3 is a detailed diagram of the boost circuit of Figure 1;

Figure 4 is a detailed diagram of the pulse width modulator of Figure 1; and

Figure 5 is a control circuit for the auxiliary power controller of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to Figure 1, the welding power source 100 includes an input rectifier 101, a boost circuit 102, a pulse-width modulator 103, a controller 104, an auxiliary power controller 105, a pair of storage capacitors C3 and C7, and their associated protective resistors R4 and R10, an output transformer T3, an output inductor L4, feedback current transformers T4 and T6, feedback capacitors and resistors C13, C14, R12 and R13, and output diodes D12 and D13 to provide a welding output current on welding output terminals 108. A cooling fan 110, a front panel 111, and a remote connector 112 are also shown schematically.

In operation, power source 100 receives a three-phase line voltage on input lines 107. The three-phase input is provided to input rectifier 101. Input rectifier 101 rectifies the three-phase input to provide a generally dc signal. A 10 microfarad capacitor C4 is

provided for high frequency decoupling of the boost circuit. The dc signal has a magnitude of approximately 1.35 times the magnitude of the three-phase input. The decoupled dc bus is provided to boost circuit 102. As will be described in greater detail below, boost circuit 102 processes the dc bus provided by input rectifier 101 to provide a dc output voltage having a controllable magnitude. In the preferred embodiment the output of boost circuit 102 will be approximately 800 volts, regardless of the input voltage.

The output of boost circuit 102 is provided to pulse-width modulator 103, where the dc bus is inverted and pulse-width modulated to provide a controllable signal suitable for transforming into a welding output. Controller 104 is a main control board such as that found in many inverter-type welding power sources. The main control board provides the control signals to pulse-width modulator 103, to control the frequency and pulse-width of pulse-width modulator 103. Input rectifier 101, pulse-width modulator 103, controller 104 and output transformer T3 are well known in the art.

The output of pulse-width modulator 103 is provided to an output transformer T3, which, transforms the output of PWM 103 to provide a voltage and current suitable for welding. Transformer T3 has a center tap secondary and is provided with a turns ratio of 32 turns on the primary to 5 turns on each half for the center tap secondary. Of course, other transformers may be used. The alternating output of transformer T3 is rectified and smoothed by an output inductor L4 and output diodes D12 and D13. Inductor L4 has an inductance sufficient to provide desirable welding characteristics, such as, for example, in a range of 50-150 microhenrys.

Auxiliary power controller 105 receives the input line voltage and converts that voltage to a 18 volt dc control signal. The 18 volt control signal is created regardless of the input voltage, and is provided to boost circuit 102. Boost circuit 102 uses the 18 volt control

signal to control its switching frequency and the magnitude of its output. Auxiliary power controller 105 also provides a 48 volt center tap ac power signal to controller 104.

5 Front panel 104 is shown schematically and is used to convey operating status to the user, as well as receive inputs as to operating parameters. Similarly, remote connector 112 is shown schematically and is used to receive inputs as to operating parameters.

10 Generally speaking, at power-up a three phase input is provided on input lines 107. A plurality of initially open contactors 115 isolates the input power from input rectifier 101. However, the input power is provided to auxiliary power controller 105. As will be
15 described in greater detail below, auxiliary power controller 105 determines the magnitude of the input power, and opens or closes a number of contacts to provide a 48 volt center tap ac output to controller 104, regardless of the input. The contacts are closed and
20 opened in such a way as to provide safeguards against underestimating the magnitude of the input voltage, and thus protecting the circuit components. Also, auxiliary power controller 105 provides an 18 volt dc control signal to boost circuit 102, regardless of the magnitude
25 of the input.

 After the voltage level has been properly determined by closing the proper contacts controller 104 causes contacts 115 to be closed, thus providing power to input rectifier 101. Input rectifier 101 includes a
30 precharge circuit to prevent a resonant overcharge from harming capacitors C3 and C7 and to avoid excessively loading of the input source. A signal received by input rectifier 101 from a tap on transformer T3 turns on an SCR (described in more detail below). The conducting SCR
35 bypasses input current around the precharge resistors.

 The output of input rectifier 101 is provided to boost circuit 102. Boost circuit 102 is well known in the art and integrated circuit controllers for boost

circuits may be purchased commercially. In operation boost circuit 102 senses the voltage at its inputs and its outputs. As will be described in more detail later and IGBT (or other switching element) is switched on and
5 off at a frequency and duty cycle (or pulse width) to obtain a desired output voltage. In the preferred embodiment the desired output voltage is approximately 800 volts.

Boost circuit 102 thus provides an output of
10 about 800 volts to 800 microfarad electrolytic capacitors C3 and C7, which have 45K ohm bleeder and balancing resistors R4 and R7 associated therewith. Capacitors C3 and C7 thus acts as a dc link for PWM 103.

PWM 103 receives a generally constant 800 dc
15 signal and modulates it to provide, after transformation, rectification and smoothing, a welding output at a user selected magnitude. PWM 103 modulates its input in accordance with control signals received from controller 104. PWM 103 also receives a 25 volt dc power signal
20 from controller 104. Such a PWM is well known and PWM 103 may be purchased commercially as a single module.

The output of PWM 103 is provided to output
transformer T3 and which transforms the relatively high voltage, low current signal to a voltage suitable for use
25 in welding. The output of transformer T3 is rectified by diodes D12 and D13, and smoothed by output inductor L4. Thus, a generally constant magnitude dc welding output is provided on welding outputs 108.

Current transformers T4 and T5, provide
30 feedback signals to controller 104, snubber capacitors C13 (0.1 microfarads) and C14 (0.022 microfarads), and snubber resistors R12 (12 ohms) and R13 (47 ohms) suppress voltage transients associated with recovery of D12 and D13. Controller 104 compares the feedback
35 signals to the desired welding current, and appropriately controls PWM 103 to adjust its switching pulse width if necessary.

Referring now to Figure 2, the preferred embodiment for input rectifier 101 is shown in detail and includes a full wave bridge comprised of diodes D4, D5, D6, D9, D10 and D11. The bridge rectifies the three phase input to provide a signal having a magnitude of about 1.35 times the input voltage magnitude. A pair of 50 ohm resistors R1 and R2 are provided to precharge capacitors C4, C3 and C7 (shown in Figure 1) upon start up. This prevents a sudden surge of current from being dumped into capacitors C4, C3 and C7.

After the precharge is completed an SCR Q1 is turned on via a signal from a tap on output transformer T3 (also in Figure 1). The signal from transformer T3 is provided to the gate of SCR Q1 via a current limiting resistor R6 and capacitor C6. A recovery diode D7 and snubber resistor R5 are provided across the gate of SCR Q1. SCR Q1 shunts the resistors and allows the maximum current flow to inductor L2 of boost circuit 102.

A plurality of varistors RV1-RV3 are provided to suppress line spikes. Additional varistors (not shown) may be provided between D9-D11 and ground to further suppress spikes.

As one skilled in the art will readily recognize, other circuits and circuit elements will accomplish the function of input rectifier 101.

Referring now to Figure 3, the details of one embodiment of boost circuit 102, which operates in a manner well known in the art, is shown. Generally speaking, boost circuit 102 provides an output voltage that is equal to the input voltage divided by one minus the duty cycle of a switch IGBT1 in boost circuit 102.

Thus, if the switch IGBT1 is off 100% of the time the output voltage (the dc link voltage) is equal to the input voltage (from capacitor C4 and input rectifier 101). In one embodiment the lowest input is about 200 volts, and the desired output (dc link voltage) is 800 volts, thus the upper limit for the "boost" is about 400%, and requires a duty cycle of about 75%.

The operation of a boost circuit should be well known in the art and will be briefly described herein. When switch IGBT1 is turned on, current flows through an inductor L2 to the negative voltage bus, thus storing
5 energy in inductor L2. When switch IGBT1 is subsequently turned off, the power is returned from inductor L2 through a diode D1 and a 14 microhenry saturable reactor L1 to the dc link. The amount of energy stored versus
10 returned is controlled by controlling the duty cycle in accordance with the formula stated above. In order for the boost circuit to operate properly inductor L2 must have continuous current, therefore inductor L2 should be
15 chosen to have a large enough inductance to have a continuance current over the range of duty cycles. In one embodiment inductor L2 is a 3 millihenry inductor. The remaining elements of boost circuit 102 include a
20 0.0033 microfarad capacitor C1, a diode D3, a 1 ohm resistor R3, a 50 ohm resistor R6, a diode D8, a 50 ohm resistor R7 and a 0.1 microfarad capacitor C8 which are primarily snubbers and help the diode recover when switch IGBT1 is turned on.

Boost circuit 102 includes an IGBT driver 301 that controls the duty cycle of switch IGBT1. Driver 301 receives feedback signals indicative of the output
25 voltage and the input current, and utilizes this information to drive switch IGBT1 at a duty cycle sufficient to produce the desired output voltage.

In one embodiment, boost circuit 102 includes a shunt S1 (shown on Figure 1). Shunt S1 provides a
30 feedback signal that is the current flowing in the positive and negative buses. A Unitrode power factor correction chip is used to implement boost circuit 102 in the preferred embodiment and requires average current flow as an input. In response to this information and
35 the dc link voltage, driver 301 turns switch IGBT1 on and off.

As one skilled in the art will readily recognize, other circuits and circuit elements will accomplish the function of boost circuit 102.

As stated above, the output of boost circuit 102 is provided to capacitors C3 and C7 (Figure 1) and is the dc link voltage. In one embodiment the dc link voltage is 800 volts, as determined by the switching of switch IGBT1. In the preferred embodiment, using the component values described herein the dynamic regulation of the dc link voltage is 80 volts from full load to no load. Static regulation is about a +/-2 volts, with a ripple of about +/-20 volts.

The dc link voltage is provided to pulse width modulator 103. PWM 103 is a standard pulse with modulator and provides a quasi-square wave output having a magnitude equal to the magnitude of the input, as would any other PWMs. Thus, the output of PWM 103 is about +400 volts to -400 volts for an 800 volt peak to peak centered about zero.

PWM 103 includes a pair of switches Q3 and Q4 (preferably IGBTs) and a pulse width driver 401. Driver 401 receives feedback from current transformers T1 and T2, and receives control inputs from controller 104. In response to these inputs driver 401 provides gate signals to switches Q3 and Q4, thereby modulating the input signal. A capacitor C2 (4 microfarad) a capacitor C9 (4 microfarad) are provided between the dc link and the output transformer T3. A capacitor C5 (0.0022 microfarad), resistor R11 (50K ohm) and resistor R9 (50K ohm) are snubber circuits.

As one skilled in the art will readily recognize, other circuits and circuit elements will accomplish the function of PWM 103.

The output of PWM 103 is provided to transformer 103, and the current in transformer 103 is determined by the modulation of PWM 103. As stated above, the output of transformer T3 is rectified by diodes D12 and D13 and is smoothed by inductor L4. The

dc output current is fairly flat; the ripple at full load (300 amps) is about 12 amps peak to peak. At full load the duty cycle of each switch Q3 and Q4 of PWM 103 would be about 20-35% (40-70% overall duty cycle).

5 In an alternative embodiment the output of PWM 103 may be rectified by other output rectifiers such as a synchronous rectifier (cycloconverter) that provides an ac output signal at a frequency less than or equal to the frequency of the output of PWM 103. Other output
10 circuits, including inverters, that provide a welding current may also be used.

Referring again to Figure 1, controller 104 is connected to current transformers T4 and T5, which provide feedback information. Controller 104 receives
15 power from auxiliary power controller 105 and provides as one of its output the driver control for the PWM driver. It also includes an over voltage protection sense which monitors the voltage coming out of input rectifier 101. If the voltage from input rectifier 101 is dangerously
20 high controller 104 causes contactors 115 to open, to protect circuit components. According to one embodiment 930 volts dc is the cut off point for what is considered to a dangerously high voltage.

As may be seen from the above description,
25 welding power source 100 receives an input voltage and provides a welding output. Regardless of the magnitude of the input voltage boost circuit 102 boosts the input voltage to a desired (800 volts e.g.) level. Then PWM 103 modulates the signal to provide an appropriate level
30 of power, at 800 volts, to transformer T3.

The above arrangement is satisfactory for any input voltage, however, there must be some mechanism to provide control voltages at the proper level. As will be described below, auxiliary power controller 105 performs
35 that function, and the embodiment thereof is shown schematically in Figure 5.

With reference now to Figure 5, a plurality of connectors J1, J2, J3 and J4 are shown. An 18 volt dc

control voltage output is provided on connector J1 to
boost circuit 102 (shown on Figure 1). As will be
described in greater detail below, the 18 volt dc control
signal is provided regardless of the magnitude of the
input voltage. Connector J2 feeds power back to
auxiliary power controller 105 for internal use.
Connector J3 connects the input ac voltage to appropriate
taps on a transformer T7 (Figure 1) to provide a 30 volt
ac signal to remote connector 112 (Figure 1). Similarly,
a 48 volt center tap ac signal is provided to controller
104. Controller 104 uses the 48 volt center tap ac
signal to generate dc control signals and to power fan
110. Connector J4 of auxiliary power controller 105 is
connected via a user controlled on/off switch S4 to the
input power lines (Figure 1).

Auxiliary power controller 105 controls the
connections to taps on the primary of an auxiliary power
transformer T7. Transformer T7 is a 200 VA transformer
whose primaries are connected to auxiliary power
controller 105 as described above with reference to
connector J2 and J3. Several taps on its secondary are
connected to controller 104 and the remaining secondary
taps are connected to remote connector 112.

Referring again to Figure 5, the taps on J3 are
associated with the following voltages: 575, 460, 380,
230 volts, and the return, beginning at the uppermost tap
and proceeding downward. As will be described below,
when auxiliary power controller 105 selects the
appropriate tap for a given input voltage, transformer T7
will provide a 48 volt center tap ac signal on its
secondary for use by controller 104.

As may be seen on Figure 5, the ac input is
received on connector J4 and provided (via a fuse F1, and
a pair of 4.7 ohm resistors R18 and R19) to a series of
relays K2B, K1B, K3C and K3B that determine the tap on
connector J3 selected for the output. When 575 volts are
present at the input relays K2B and K3C should be to the
right. Then the input is connected across the upper and

lower most taps on connector J3. These taps are connected to the appropriate taps on transformer T7 such that the output of transformer T7 that is provided to controller 104 is approximately 48 volts center tap when
5 575 volts are provided to the primary of transformer T7.

When 460 volts are present at the input relay K2B should be to the left, and relay K1B should be to the right. This connects the ac input to the second
10 uppermost and the lowest taps on connector J3. The remaining voltages are similarly accommodated. A pair 0.15 microfarad capacitors C13 and C14 are provided for snubbing and spike suppression as the primaries of transformer T7 are switched.

In operation the circuitry on the left side of
15 Figure 5 determines the input voltage, and sets the relays for that voltage. At start up the relays are as shown in Figure 5 and are suitable for an input voltage of 575 volts. Because this is the highest possible input voltage, all components will be protected, i.e. either
20 the voltage is properly selected, or the input voltage is less than the component design capabilities. If auxiliary power controller 105 determines that 575 volts are in fact present, the relays will remain as shown. However, if auxiliary power controller 105 determines
25 that less than 575 volts are present, the state of relay K2B will be changed (to be to the left), so that the output is appropriate for a 460 volt input.

This process is repeated, always stepping down to the next highest voltage, until the appropriate input
30 voltage is sensed. In this manner the components in controller 104 will be protected from a dangerously high voltage being applied to controller 104.

The voltage for sensing is provided to auxiliary power controller 105 via connector J2, which is
35 connected to secondary taps on transformer T7. Thus, if the tap selected on connector J3 was not correct, then the voltage on connector J2 will be too low, and auxiliary power controller 105 will select the

appropriate relay setting to step down to the next voltage level. As stated above, the stepping down continues until the proper voltage is sensed on connector J2.

5 The input from connector J2 is provided to a rectifier comprised of diodes CR1, CR2, CR3 and CR4. These diodes rectify the ac signal and provide it to a pair of 220 microfarad smoothing capacitors C1 and C2. The rectified voltage is +/-18 volts dc if the proper tap on connector J3 is selected. If the incorrect tap is selected the voltage will be less than +/-18 volts, but will be referred to as nominally +/-18 volts. The nominal +/-18 volt supply is provided at other locations throughout the auxiliary power controller 105 circuit, including to a 30 volt zener diode CR7, used to determine if the proper tap on connector J3 has been selected.

15 Auxiliary power controller 105 determines if 575 volts is present on the input using the following components: zener diode CR7, a 10 microfarad capacitor C9, a pair of gates U2B and U2C configured as darlington drivers for a winding K2A of relay K2, a 10K ohm resistor RN2A, a 10K ohm resistor RN2B, a 820 ohm resistor R9, and a diode U3B. Gates U2B and U2C are also used as sensing devices and have a threshold of about 4 volts (relative to their reference voltages) on the input (pin 1) of gate U2B pin 1.

25 Initially, gate U2B has a LOW output and is referenced to nominal -18 volts. Gate U2B will not switch states so long as the input is at least 4 volts greater than its reference voltage (nominally -18 volts relative to ground). In operation the nominal +18 volts will be provided to diode CR7 and the nominal -18 volt signal is applied to a 10 microfarad capacitor C9. As a result of the 30 volt zener drop, the input to gate U2B will be at -12 volts (relative to ground) if the proper tap has been selected. If 575 volts are present at the input, there will be 6 volts relative to the reference voltage (-18 volts) at the input to op amp U2B, and the

output state of gate U2B will remain low. So long as the output of U2B remains low the current will not flow in the winding of relay K2 and relay K2B will remain as shown in Figure 5.

5 However, if only 460 volts are present on the input and the relays are as shown in Figure 5 (as they will be at power up), then the nominal +/-18 volts will actually be +/-14.4 volts. Thus, 28.8 volts are applied across zener diode CR7 and capacitor C9. Given the 30
10 volt zener drop, -14.4 volts will be applied to the input of gate U2B. Because this is also the reference voltage for gate U2B, the threshold is crossed, and the output of gate U2B will change states. Current will then flow in the winding of relay K2 and relay K2B will change states,
15 configuring the J3 taps for 460 volts. If less than 460 volts is present at the input the same result will occur.

 The sensing and stepping down to 380 volts and 230 volts occur in a similar manner using similar components. Referring to Figure 5, the sense and step
20 down circuit to 380 volts include a 100 ohm resistor R17, a pair of 10K ohm resistors RN2C and RN2D, an 820 ohm resistor R8, a diode U3C, a 10 microfarad capacitor C6, a pair of gates U2D and U2E, and a winding K1A for relay K1. A relay K2C is provided to prevent relay K1 from
25 changing states before the step down to 460 volts occurs. In the manner described above with respect to the step down to 460 volts, the current will be provided to winding K1A of relay K1 if less than 460 volts is provided at the input. This will cause relay K1B to move
30 to the left position and connect the tap on J3 associated with a 380 volt input.

 The circuitry associated with the step down to 230 volts includes a 100 ohm resistor R16, a pair of 10K ohm resistors RN1A and RN1B, an 820 ohm resistor R11, a
35 diode U3E, a pair of gates U2F and U2G, a winding K3A for relay K3, relay K1C, diode CR5 and zener diode CR4. A relay K1C is provided to prevent relay K3 from changing states before the step down to 380 volts occurs. The

step down to 230 volts operates in the same manner as the step down to 380 volts and 460 volts as described above. If less than 380 volts is applied on the connector J4 inputs, gates U2F and U2G will cause current to flow through winding K3A of relay K3. This will cause relay K3B to move to the left and connect the tap on J3 for 230 volts to the ac input.

Thus, as may be seen from the above description, the circuitry of auxiliary power controller 105 senses the ac input voltage and connects the appropriate tap on the auxiliary power transformer T7 to the ac input voltage. As may be seen from the above discussion, this is done in a manner which protects components by assuming the voltage is, upon start up, the highest possible voltage. If the voltage is less than the highest possible voltage, the next lowest voltage will then be assumed. This process is repeated until the actual voltage is obtained.

In the event that the ac input is 230 volts, at start up there will not be sufficient power from the nominal ± 18 volt signal to drive the relays because the tap associated with 575 volts on connector J3 is selected at start up. To compensate for this, circuitry that boosts the voltage supplied on connector J2 is provided. This circuitry includes a 1 millihenry inductor L1, a switch Q4, a timer U1, a switch Q2, a switch Q1, and a switch TIP120. Also included are associated circuitry including a 22 ohm shunt resistor R13, a 1K resistor R5, a 10K resistor R12, a 10K resistor R14, a 2.2K resistor R4, a 1K resistor R6, a 1K resistor R2, a 20K resistor R3, a 220 ohm resistor R7, a 10K resistor RN1D, a 4.7K resistor R10, a 470 picofarad capacitor C4, a .001 microfarad capacitor C3, a 0.1 microfarad capacitor C5, a 220 microfarad capacitor C11, a 220 microfarad capacitor C12, a diode CR12, a diode CR8, a zener diode CR10, a diode CR5, and a zener diode CR11.

The boost power source circuitry operates as a typical boost circuit. The boost is provided by inductor L1 and switch Q4. During the time switch Q4 is ON, current flows through inductor L1, shunt resistor R13 and switch Q4 to the negative voltage supply. During this time, energy is stored in inductor L1. When switch Q4 is OFF, the energy stored in inductor L1 is returned to the positive voltage supply (+B) through diode CR12. By appropriate timing of the turning ON and OFF of switch Q4, a desired voltage may be obtained. Timer chip U1 is used to provide the ON/OFF gate signals to switch Q4 and is an LM555 timer. When the voltage on resistor R13 becomes sufficiently high, it will trip the input on U1, which in turn will cause the output of timer U1 to turn switch Q1 OFF.

Initially, switch Q4 is in the ON position and current increases and eventually reaches the point where the voltage on resistor R13 is sufficiently high to trip the threshold on timer U1 through resistor R12. Thus, switch Q4 will remain ON for a length of time sufficient to build up enough energy to, when it is turned OFF, raise the nominal +/- 18 volts to a level sufficient to drive the relays.

Switches Q2 and Q1 enable or disable timer U1 when the taps on connector J3 are such that the nominal +/- 18 volt signal is actually +/- 18 volts. When switch Q2 is turned OFF, timer U1 is disabled through its VCC input. Also, switch TIP120 is a linear regulator. When the nominal +18 volt supply is insufficient to drive the relay, switch TIP120 will provide the boost source to drive the relays. When the nominal +18 voltage is sufficient to drive the relay, switch Q2, timer U1 and switch Q4 are turned off. The +18 volt supply is coupled through L1 and CR12 to regulator TIP120; the +B boost supply is then fed directly by the sufficiently high +18 volt supply. The TIP120 regulator regulates relay supply at 24 volts relative to the ~~18~~ volt supply.

In addition to the circuitry above, circuitry is provided that protects in the event of an overvoltage. This circuitry includes a switch Q5, a gate U2A, a 100 ohm resistor R15, a 10K ohm resistor RN3A, a 10K ohm resistor RN3B, a 10K ohm resistor RN3C, a 10 microfarad capacitor C10, diodes CR14 and U3H, and 10 volt zener diode CR13. An overvoltage occurs when the tap selected on connector J3 corresponds to a voltage less than the voltage at the ac input. This may occur when either the incorrect tap has been selected or when a temporarily high voltage is provided at the ac input.

In the event an overvoltage occurs, the voltage at the node common to diodes CR13 and CR7 will rise to a voltage greater than 14 volts with respect to the nominal -18 volt signal. This causes the low side of diode CR13 to be greater than 4 volts with respect to the nominal -18 volt signal, and the input of U2A will change from an input low state to an input high state. When the input of U2A changes from low to high, the output will change from an output high state to an output low state. The output low state of U2A will bring the relay supply voltage to a virtual 0 through diodes U3H and CR14. This causes the relays to return to the state shown in Figure 2, which accommodates the highest voltage possible (575 volts). At that time the previously described tap selection process stepping from the 575 to 460 to 380 to 230 taps begins again until the correct tap is selected to match the input voltage received on connector J4. Accordingly, the components of controller 104 will be protected.

Other modifications may be made in the design and arrangement of the elements discussed herein without departing from the spirit and scope of the invention as expressed in the appended claims.

CLAIMS

I claim:

1 1. A welding power source capable of
2 receiving a range of input voltages, comprising:
3 an input rectifier configured to receive an ac
4 input and providing a first dc signal;
5 a dc voltage stage configured to receive the
6 first dc signal and providing a second dc signal;
7 an inverter configured to receive the second dc
8 signal and providing a second ac signal and
9 configured to receive at least one control input;
10 an output transformer configured to receive the
11 second ac signal and providing a third ac signal
12 having a current suitable for welding;
13 an output circuit configured to receive the
14 third ac signal and providing a welding signal;
15 a controller configured to provide at least one
16 control signal to the inverter; and
17 an auxiliary power controller configured to
18 receive a range of input voltages and providing a
19 control power signal to the controller.

1 2. The apparatus of claim 1, wherein the
2 auxiliary power controller is capable of providing the
3 control power signal at a preselected control signal
4 voltage, regardless of the magnitude of the ac input
5 signal.

1 3. The apparatus of claim 2, further
2 including an auxiliary transformer with a plurality of
3 primary taps, wherein the auxiliary power controller is
4 in electrical communication with the plurality of primary
5 taps.

1 4. The apparatus of claim 1, wherein the dc
2 voltage stage includes a boost circuit.

1 5. The apparatus of claim 1, wherein the
2 inverter includes a pulse width modulator.

1 6. The apparatus of claim 1, wherein the
2 range of input voltages is 230 volts to 575 volts.

1 7. The apparatus of claim 1 wherein the
2 output circuit includes a rectifier.

1 8. The apparatus of claim 1 wherein the
2 output circuit includes a cycloconverter.

1 9. A method of providing a welding current
2 from a range of input voltages, comprising:
3 rectifying an ac input and providing a first dc
4 signal;
5 converting the dc signal to a second ac signal;
6 transforming the second ac signal into a third
7 ac signal having a current suitable for welding; and
8 receiving the ac input and providing an
9 auxiliary power signal source at a preselected
10 control power signal voltage, regardless of the
11 magnitude of the ac input signal.

1 10. The method of claim 9, wherein the step of
2 converting the dc signal includes the steps of converting
3 the dc signal to a second dc signal and inverting the
4 second dc signal to provide the second ac signal.

1 11. The method of claim 9 further including
2 the step of providing control signals to an inverter.

1 12. The method of claim 9, wherein the step of
2 providing the auxiliary power signal includes the step of
3 transforming the ac input signal.

1 13. The method of claim 10, wherein the step
2 of converting the first dc signal to a second dc signal
3 includes boosting the voltage of the first dc signal.

1 14. The method of claim 10, wherein the step
2 of inverting includes the step of pulse width modulating.

1 15. The method of claim 10 further including
2 the step of rectifying the third ac signal.

1 16. The method of claim 10 further includes
2 the step of cycloconverting the third ac signal.

1 17. A welding power source for providing a
2 welding current from a range of input voltages,
3 comprising:

4 rectifier means for receiving an ac input and
5 providing a first dc signal;

6 converting means for converting the dc signal
7 to a second ac signal;

8 transforming means for transforming the second
9 ac signal into a third ac signal having a current
10 suitable for welding;

11 output means for providing a welding current;
12 and

13 auxiliary power means for receiving the ac
14 input and providing an auxiliary power signal at a
15 preselected control power signal voltage, regardless
16 of the magnitude of the ac input signal.

1 18. The apparatus of claim 17, wherein the
2 means for converting includes means for converting the dc
3 signal to a second dc signal and means for inverting the
4 second dc signal to provide the second ac signal.

1 19. The apparatus of claim 17 further
2 including means for providing control signals to an
3 inverter.

1 20. The apparatus of claim 17, wherein the
2 means for providing the auxiliary power signal includes
3 means for transforming the ac input signal into the
4 auxiliary power signal.

1 21. The apparatus of claim 17, wherein the
2 means for converting the dc signal to a second dc signal
3 includes means for boosting the voltage.

1 22. The apparatus of claim 17, wherein the
2 means for inverting includes means for pulse width
3 modulating.

1 23. The apparatus of claim 17, wherein the
2 output means includes means for rectifying the third ac
3 signal.

1 24. The apparatus of claim 17, wherein the
2 output means includes means for cycloconverting the third
3 ac signal.

ABSTRACT OF THE DISCLOSURE

A method and apparatus for providing a welding current is disclosed. The power source is capable of receiving any input voltage over a wide range of input
5 voltages and includes an input rectifier that rectifies the ac input into a dc signal. A dc voltage stage converts the dc signal to a desired dc voltage and an inverter inverts the dc signal into a second ac signal. An output transformer receives the second ac signal and
10 provides a third ac signal that has a current magnitude suitable for welding. The welding current may be rectified and smoothed by an output inductor and an output rectifier. A controller provides control signals to the inverter and an auxiliary power controller that
15 can receive a range of input voltages and provide a control power signal to the controller.

DECLARATION AND POWER OF ATTORNEY

As a below named inventor, I hereby declare: THAT my residence, post office address and citizenship are as stated below next to my name; THAT I verily believe I am the original, first and sole (if only one name is listed below) or a joint inventor (if plural inventors are named below) of the invention entitled: METHOD AND APPARATUS FOR RECEIVING A UNIVERSAL INPUT VOLTAGE IN A WELDING POWER SOURCE of the specification of which:

☒ is attached hereto.

☐ was filed on _____ as Application Serial No. _____ and was amended on _____ (if applicable).

☐ is amended in the attached Amendment.

THAT I do not know and do not believe that this invention was ever known or used in the United States of America before my or our invention or discovery thereof, or patented or described in any printed publication in any country before my or our invention or discovery thereof, or more than one year prior to this application;

THAT the invention was not in public use or on sale in the United States of America for more than one year prior to this application;

THAT this invention has not been patented or made the subject of an inventor's certificate issued before the date of this application in any country foreign to the United States of America on an application filed by me or my legal representatives or assigns more than twelve months before this application,

THAT I have reviewed and understand the contents of the above identified specification, including the claim(s), as amended by any amendment referred to above;

THAT I acknowledge the duty to disclose information of which I am aware which is material to the examination of this application in accordance with 37 CFR §1.56; and

THAT applications for patent or inventor's certificate on this invention or discovery which have been filed by me or my legal representatives or assigns in any country foreign to the United States of America are as follows (leave blank if none):

(a) none filed more than 12 months prior hereto, unless identified here: _____, or

(b) earliest filed less than 12 months prior hereto the priority of which is hereby claimed under 35 U.S.C. 119. The foreign application(s) on which priority is claimed is: _____; and other foreign applications having filing dates earlier than the application(s) on which priority is claimed are as follows: _____.

AND I hereby appoint, as my attorneys to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith and with the resulting patent; each attorney named below with Registration Number; individually and collectively:

Foley & Lardner
777 East Wisconsin Avenue
Milwaukee, Wisconsin 53202

telephone number (414) 271-2400 (to whom all communications regarding the subject application are to be directed); and each attorney thereof named below with Registration Number, and of the same address:
